POPULATION PROJECTIONS FOR SOUTH CAROLINA BY COUNTY

1985, 1990, 1995, 2000, 2005, 2010

South Carolina State Data Center

July 1, 1986

I. INTRODUCTION

Future population trends must be considered in guiding long-term socioeconomic planning in order for that planning to be effective. Planners should be concerned not only with the absolute numbers (future size), but also the composition of that population. Population projections by age and sex are necessary for planning at the national, state, and local levels.

The specific objective of this study is to project the population of South Carolina by counties for the period 1985-2010. Projections are done in five-year intervals over the period and data are broken out into race, sex, and five-year age groups through age eighty-five.

II. METHODOLOGY

There are several possible methods of estimating future population, among them are time series analysis, "shift-share" analysis, regression, economic models, trend analysis, component models, etc. Mathematical and economic models are traditionally known as forecasts but can also be stated as point estimates. While mathematical models employ certain statistical procedures for estimating future population, economic models calculate population growth as it depends upon future economic conditions. Projections, however, are based on historic trends. There are three principal ways of projecting:

- project the total amount of growth of a given period,
- project an observed rate of growth,
- project the size of age and sex groups of the population independently (commonly known as the cohort component method).

The Division of Research and Statistical Services uses the cohort component model to project population. Population is projected forward by five-year age-sex cohorts utilizing rates for the three components of population change: fertility, mortality, and migration.

Projections are county specific, i.e., each county is projected independently of other counties. County populations are then summed to produce the total state population. While no attempt was made to control the populations to a predetermined state total, checks were made to bring the 1985 county totals in line with the extrapolation of the 1981-1984 Census estimates. These adjustment factors were continued through the projected period. The 1980 Census population was used as the base; projections were then completed in five-year intervals starting at 1985 and ending with 2010.

A. Review of Historic Trends

Before each of the components was examined and rates determined, state population trends from 1960 to the present were reviewed and two previous projection series

(Population Projections for South Carolina by County 1985, 1990, 1995, 2000, Division of Research and Statistical Services; Provisional Projections of the Population of States, by Age and Sex: 1980 to 2000, Bureau of the Census) were studied. Using data from the previous projection series and the three previous Census populations, several shiftshare scenarios were produced for 1984. (Shiftshare is a descriptive technique normally used in the field of economics to present components of regional growth). These scenarios were compared to the 1984 Census estimate. In all of these scenarios, the shiftshare coastal areas did not match the magnitude of growth that the Census Bureau had shown for 1980-1984. If these Census Bureau estimates are accepted, no pure mathematical or economic model could clearly capture population growth, particularly in the coastal areas. Thus, each of the population components must be examined separately.

B. Fertility

Data on the number of live births by age and race from 1960 to 1983 were obtained from the South Carolina Department of Health and Environmental Control (DHEC). With slight variations, statewide crude birthrates have steadily declined from 1960 to the present. Age-specific fertility rates for women in childbearing years (split into six five-year groups for women between fifteen and forty-four) were calculated for the years 1970-1983. (After further study, the age group ten to fourteen was also added). A curvilinear trend was used to determine five year statewide age-specific fertility rates out to the year 2010.

Predicted 1980-1985 births were checked against expected births (births were extrapolated from actual reported births for the calendar years 1980 through 1983) of the county and state levels. Adjustments were made to pull the predicted births to within five percent of the actual number of births.

The sex ratio was calculated by taking the mean of live births by sex as reported by DHEC over a five-year period (1979-1983). Both the sex ratio and county specific adjustment factors were maintained throughout the projection period.

Once the total number of births was projected for each county in each five-year interval, they were modified using sex-specific survival rates. These modified births then become the zero to four population group at the beginning of the next projection interval.

C. Mortality

The second component of the projection methodology is associated with the survival characteristics of the population structure. Specific survival life tables by age, race and sex for a five-year period were utilized to age the population through time. These tables were the "middle series" used by the Census Bureau in its national population projections. These rates of change were based upon projections completed by

the Social Security Administration and assumed a slight continued decline in mortality rates.

Predicted 1985 deaths (based on survival rates) were compared to expected 1985 deaths (based on extrapolation from actual reported deaths for the calendar years 1980 through 1983). A separate check was completed on predicted deaths of infants under one year of age against expected deaths. National survival rates proved to be higher than the South Carolina rates. Therefore, adjustments were made to the survival rates to reflect more deaths. These rates produced the acceptable number of deaths (within five percent of the 1980-1985 deaths).

D. Migration

Net migration rates were calculated after thorough analysis of patterns of migration from 1975-1980 (data from Census of Population, 1980 tape on county to county migration flows). These rates were based on movement to and from counties regardless of origin. In each county, rates were broken down further by race, age, and sex. A separate check was made on those counties with a high military population. Military net migration rates were calculated for each "high military" county and compared to the total net migration rates for that county. No extreme variations were noted in this comparison.

Predicted 1985 migrants (based on the total net migration rates) were compared to expected 1985 migrants (based on the extrapolation of the Census estimate of 1980-1984 migration). Revisions were necessary in the coastal areas.

After producing the population projections, some general changes can be noted. These changes result from overall aging of the population and the migration patterns for South Carolina.

1. Similar to the experience of Florida in the 1950's, South Carolina is starting to have explosive growth in the coastal counties. The "baby boomers" will be retiring in great numbers to the Sunbelt after the turn of the century.

2. By the turn of the century, the White population growth will be largely accomplished by in-migration. These Whites will tend to be retirement age individuals

3. The labor force will move from 35% Nonwhite in 1985 to 40% Nonwhite in 2010. This trend will continue through time.

4. In 2010 the retirement age group will be predominantly composed of out-of-state White migrants. This group will demand services based on their past experiences with more comprehensive state governments.
